e⁻ linac design

Summary

TcMM

- Developed by **Kaken Inc., Mito, Japan**
- Can be used with both LSA- and HSA-⁹⁹Mo
- Uses two columns of:
 - **Activated carbon (AC)**, which **adsorbs Tc(VII) oxoanions** but not Mo(VI) ones (opposite of alumina)
 - **Activated alumina (AA)**, which **adsorbs Mo(VI) oxoanions** in the eluate of Tc(VII) oxoanions
- Exhibits ^{99m}Tc elution efficiencies of $\geq 90\%$ ^[2]
- Consists of six steps; these will be explained step by step

Summary

2.0-g AC column

Activated carbon (AC)

- Has a high surface-to-volume ratio
- Used in purifying air and water, etc.
- Adsorbs $[\text{TcO}_4]^- (aq)$ ions but not $[\text{MoO}_4]^{2-} (aq)$ ones

Why?

The principle of selective adsorption of $[\text{TcO}_4]^- (aq)$ to AC remains unclear; we are investing and planning experiments.

- The 200-mL $\text{Na}_2\text{MoO}_4 (aq)$ solution, containing $[\text{MoO}_4]^{2-} (aq)$ constantly decaying to $[\text{TcO}_4]^- (aq)$, was poured into the AC column.
- $[\text{TcO}_4]^- (aq)$ ions, where Tc consists of ^{99m}Tc and a small amount of ^{99g}Tc , were then tightly bound to the AC, while only marginal amounts of the $[\text{MoO}_4]^{2-} (aq)$ ions, where Mo consists of various Mo isotopes, were captured by the AC.

Summary

2.0-g AC column

- The minute amounts of $[\text{MoO}_4]^{2-}(aq)$ ions were flushed into the poured $\text{Na}_2\text{MoO}_4(aq)$ solution with $\text{H}_2\text{O}(l)$ and $\text{NaOH}(aq)$.
- The $\text{Na}_2[^{99}\text{Mo}]\text{MoO}_4(aq)$ solution was then allowed to decay to $\text{Na}[^{99\text{m}}\text{Tc}]\text{TcO}_4(aq)$ and poured again into the AC column.

X-band e^- linac dedicated to ^{99}Mo production

[1,2]

- Commissioned in 1965, the KURRI L-band electron linac is used for experiments and education; an electron linac dedicated to ^{99}Mo production is necessary.
- We have **designed such a ^{99}Mo -producing electron linac**, downsized by adopting X-band radio frequency.
- Design beam energy and power (average) are **35 MeV and 9.1 kW**, respectively^[1-2].
- 11 of the designed electron linac can meet the Japanese $^{99}\text{Mo}/^{99\text{m}}\text{Tc}$ demand^[1].

[1] J. Jang, M. Yamamoto, and M. Uesaka (2017), Design of an X-band electron linear accelerator dedicated to decentralized $^{99}\text{Mo}/^{99\text{m}}\text{Tc}$ supply: From beam energy selection to yield estimation, *Phys. Rev. Accel. Beams* 20(10) 104701.

Summary and future work

⁹⁹Mo prod.

Why MoO₃

MoO₃(γ, n)

^{99m}Tc sep.

TcMM process

(six steps)

¹⁰⁰Mo recovery

e⁻ linac design

Summary

Summary

- We use MoO₃ because of its simpler dissolution and easier pelletization compared with those of metallic Mo.
- TcMM can extract ^{99m}Tc from photonuclear-produced LSA-⁹⁹Mo as well as fission-produced HSA-⁹⁹Mo with an average elution efficiency of $\geq 90\%$, and is ready for commercialization.
- We designed a compact X-band electron linac dedicated to decentralized ⁹⁹Mo production; 11 such linacs can make Japan self-sufficient in ⁹⁹Mo/^{99m}Tc.

Current work

- The principle of [TcO₄]⁻(aq) adsorption to AC remains elusive; we are investigating and planning experiments.
- Recovering non-activated ¹⁰⁰Mo from a spent Na₂MoO₄(aq) solution is also under investigation.

Thank you for attention

Low specific activity of $^{100}\text{Mo}(\gamma, n)^{99}\text{Mo}$

$$A_{\text{Mo}}(t_{\text{irr}} = 72\text{h}) = 687 \text{ GBq}$$

Monte Carlo simulation
results at 35 MeV, 260 μA ,
and $\mathcal{V} = 1 \text{ cm}^3$

$$A_{\text{sp},i} = \frac{A_i}{m_i + \sum_{j \neq i} m_j}$$

$A_{\text{sp},i}$: specific activity of a radionuclide i

A_i : activity of a radionuclide i

m_i : mass of a radionuclide i

m_j : mass of all nuclides (stable
or radioactive) **isotopic** with i

Mo mass density $\rho = 10.2 \text{ g cm}^{-3}$

Mo target volume $\mathcal{V} = 1 \text{ cm}^3$

$$A_{\text{sp},\text{Mo}}(72 \text{ h}) = \frac{687 \text{ GBq}}{10.2 \text{ g}} = 67.35 \text{ GBq/g}$$
